ACKNOWLEDGEMENT

We would like to express our sincere and heartfelt gratitude to all those who have contributed to the successful completion of **Project Phase 2**. This milestone would not have been possible without the unwavering support, guidance, and encouragement we received from various individuals throughout this journey.

First and foremost, we extend our profound thanks to our esteemed project guide and coordinator, **Prof. Syed Saqlain Ahmed**, for his invaluable mentorship. His continuous support, insightful suggestions, and constructive feedback were instrumental in refining our ideas and steering our efforts in the right direction. His dedication and commitment to nurturing our skills served as a constant source of motivation and played a pivotal role in shaping the foundation of our project.

We are deeply grateful to **Dr. Veerendra Dakulagi**, Head of the Department of CSE (Data Science), for his generous support, encouragement, and for providing us with all the essential resources and facilities required to carry out our project work seamlessly. His leadership and dedication to academic excellence have created an environment conducive to innovation and learning.

Our sincere appreciation also goes to our respected Principal, **Dr. Dhananjay M**, Guru Nanak Dev Engineering College, Bidar, for fostering a vibrant and inspiring academic atmosphere. We are especially thankful for the state-of-the-art infrastructure, well-equipped labs, and other institutional resources that enabled us to carry out our project work efficiently. His constant encouragement and visionary leadership continue to inspire students to strive for excellence.

We would also like to take this opportunity to recognize the dedication and hard work of our **project team members**. The success of this phase is a result of our collective efforts, mutual cooperation, and the spirit of teamwork that each member displayed throughout the project. Every challenge was turned into a learning opportunity because of the synergy we shared.

Chapter 1

1.1 Introduction

Parkinson's Disease (PD) stands as one of the most pervasive and debilitating neurodegenerative disorders affecting the global population, second only to Alzheimer's disease in prevalence. It is a chronic and progressive illness, primarily characterized by a range of motor symptoms including tremors, rigidity, bradykinesia (slowness of movement), and postural instability. Over time, these motor impairments become increasingly severe, significantly impacting the quality of life of those affected. However, Parkinson's is not limited to motor disturbances alone; it also encompasses a spectrum of non-motor symptoms that may include depression, cognitive decline, olfactory dysfunction, speech irregularities, sleep disturbances, and autonomic system failures. These non-motor symptoms often precede the motor symptoms by several years, yet are commonly overlooked in conventional diagnostic practices. The pathophysiology of PD is associated with the progressive loss of dopaminergic neurons in the substantia nigra, a region in the midbrain responsible for the regulation of voluntary motor movements. The resultant dopamine deficiency leads to the impairment of neural pathways that coordinate movement, ultimately manifesting in the classical symptoms of the disease.

Despite extensive research spanning decades, the exact cause of Parkinson's Disease remains elusive. A combination of genetic susceptibility and environmental exposures is generally accepted as the underlying etiology. Mutations in specific genes such as SNCA, LRRK2, and PARK2 have been implicated in familial forms of PD, while environmental factors like prolonged exposure to pesticides, heavy metals, or traumatic brain injury have been linked to sporadic cases. Age remains the most significant risk factor, with the majority of diagnoses occurring in individuals over the age of 60. However, early-onset Parkinson's, defined as diagnosis before the age of 50, is not uncommon and presents unique challenges in terms of diagnosis, management, and prognosis. Given the irreversible nature of neuronal degeneration and the progressive course of the disease, early detection is of paramount importance in mitigating symptom severity and delaying functional decline. This forms the foundation for an emerging paradigm in Parkinson's research and clinical care—shifting the focus from symptomatic treatment to early, preclinical detection and intervention.

Traditionally, Parkinson's Disease is diagnosed based on clinical evaluation of motor symptoms, often supplemented by neurological examination and the patient's medical history. Neurologists rely heavily on tools such as the Unified Parkinson's Disease Rating Scale (UPDRS), DaTscan imaging, and physical examination to confirm their suspicions. However, these diagnostic approaches come with inherent limitations. They are largely subjective, dependent on the clinician's expertise, and often lack the sensitivity required to detect the disease in its nascent stages. Imaging techniques like positron emission tomography (PET) and single-photon emission computed tomography (SPECT) are expensive and not readily accessible in many parts of the world, especially in developing countries. Moreover, by the time clinical symptoms manifest clearly enough to support a definitive diagnosis, significant and irreversible neuronal damage has already occurred. In fact, research indicates that by the time a person presents with noticeable motor symptoms, they may have already lost more than 60% of the dopamine-producing neurons in the substantia nigra. This delay in diagnosis severely limits the window of opportunity for early therapeutic intervention and highlights a critical need for novel diagnostic approaches that can detect PD at a much earlier stage—ideally before the onset of clinical symptoms.

Recent advances in artificial intelligence (AI) and data science have ushered in a new era of precision medicine, where computational models are capable of performing complex analyses on vast datasets to derive insights that surpass human capability. Within this technological landscape, machine learning (ML) has emerged as a particularly powerful tool in the field of medical diagnostics. Machine learning algorithms can automatically learn from data, identify hidden patterns, and make predictions or decisions without being explicitly programmed. In contrast to traditional statistical methods, ML models are adept at handling high-dimensional, non-linear data, making them ideal for analyzing the multifaceted and often subtle indicators of Parkinson's Disease. Applications of ML in healthcare are expanding rapidly, with successful implementations in areas such as cancer detection, diabetic retinopathy screening, cardiovascular risk prediction, and genomic data analysis. The incorporation of ML into PD diagnostics represents a significant leap forward in our ability to detect the disease at an early stage and monitor its progression with precision and objectivity.

In the context of Parkinson's Disease, machine learning has been employed to analyze a variety of data types, including medical imaging, gait dynamics, handwriting analysis, electroencephalogram (EEG) readings, and most notably, voice recordings. Among these, voice data has garnered considerable attention as a particularly promising biomarker for early PD detection. The rationale behind this lies in the fact that the disease often affects the vocal cords, respiratory muscles, and the neural pathways involved in speech production. These physiological changes manifest as alterations in the acoustic properties of speech, such as increased jitter (frequency variation), shimmer (amplitude variation), reduced pitch range, vocal tremors, and changes in articulation rate. Importantly, these vocal anomalies can occur long before the more noticeable motor symptoms become apparent, offering a valuable opportunity for early diagnosis. The analysis of voice data for PD detection is not only non-invasive and cost-effective but also scalable and suitable for remote assessment, making it highly practical for implementation in both clinical and non-clinical settings.

In recent years, researchers have developed various machine learning models that utilize these vocal features to classify individuals as either PD patients or healthy controls. The process typically involves the collection of voice recordings from participants, extraction of relevant acoustic features using tools such as Praat or OpenSMILE, and the application of supervised learning algorithms to train classification models. Algorithms such as Support Vector Machines (SVM), k-Nearest Neighbors (k-NN), Decision Trees, Random Forest, and Gradient Boosting Machines (GBM) have all been evaluated for this task. Ensemble methods like Random Forest and XGBoost, in particular, have demonstrated superior performance due to their robustness against overfitting and ability to capture complex, non-linear relationships in the data. These models are trained on labeled datasets and subsequently tested on unseen data to evaluate their accuracy, sensitivity, specificity, and overall predictive capability. In numerous studies, voice-based ML models have achieved classification accuracies exceeding 90%, underscoring their potential as reliable diagnostic tools.

This project builds upon the growing body of research in this domain by implementing and comparing two high-performance machine learning algorithms—Random Forest and XGBoost—for the purpose of Parkinson's Disease prediction using voice data. The project involves the use of a publicly available dataset consisting of biomedical voice

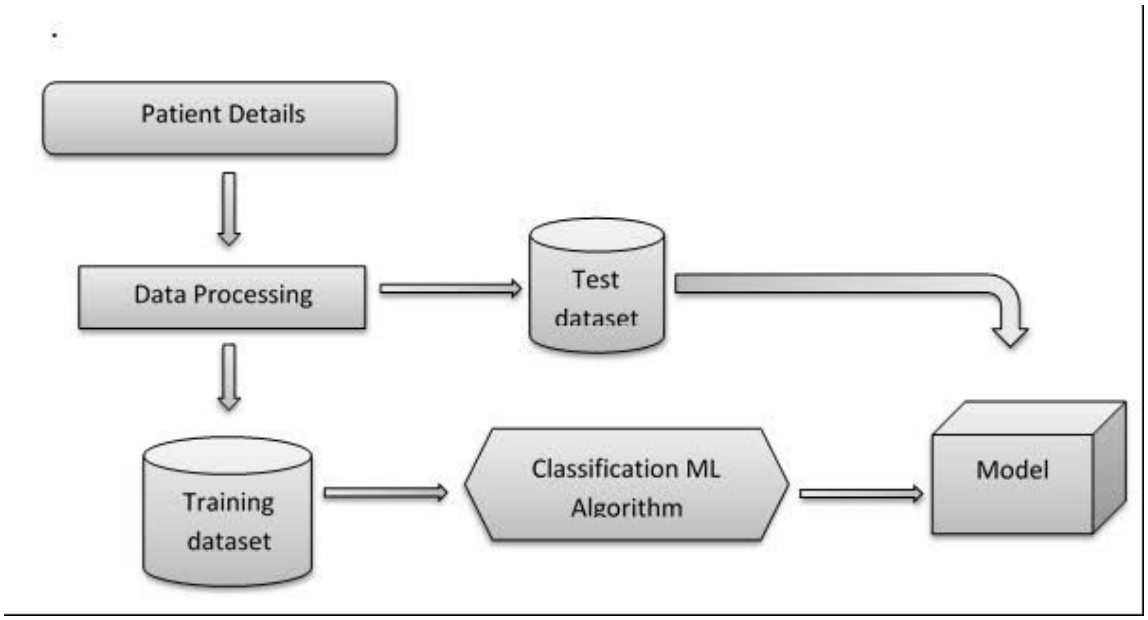
measurements collected from individuals with and without Parkinson's. These features include fundamental frequency, jitter, shimmer, harmonic-to-noise ratio, and other relevant acoustic metrics. The dataset is preprocessed to remove noise and missing values, and the data is split into training and test sets to ensure robust model evaluation. Feature scaling and selection techniques are employed to enhance model performance, and various metrics such as accuracy, precision, recall, F1-score, and confusion matrix are used to assess the efficacy of the trained models.

The motivation for this work stems from the urgent need for accessible, objective, and early diagnostic tools for Parkinson's Disease, particularly in resource-limited settings. Traditional diagnostic pathways are often inaccessible to patients in rural or underserved regions due to cost, lack of specialized healthcare providers, and logistical constraints. By contrast, a machine learning-based system that utilizes simple voice recordings—potentially even collected via a smartphone—offers a scalable and democratized approach to disease screening. Such a system could be integrated into mobile health (mHealth) applications, telemedicine platforms, or primary care workflows to facilitate early detection and continuous monitoring of PD. Moreover, this approach aligns with the broader vision of digital health, wherein technology is leveraged to empower patients, enhance healthcare delivery, and reduce the global burden of chronic diseases.

This project also seeks to contribute meaningfully to the interdisciplinary field that intersects computer science, data science, and healthcare. By exploring the practical application of machine learning techniques in a real-world biomedical context, the study not only demonstrates the power of these tools but also addresses important considerations related to data quality, model interpretability, and ethical deployment. Issues such as data privacy, algorithmic bias, and the need for explainable AI are critically relevant in the healthcare domain, where decisions can have life-altering consequences. As such, the development and deployment of ML-based diagnostic systems must be guided by principles of transparency, accountability, and patient-centric design.

Chapter 2

2.1 Block Diagram



1. Patient Details

This block represents the input data collected from patients. It includes various features such as:

Medical history

Clinical symptoms

Biomedical voice measurements (for Parkinson's)

Demographic information (age, gender, etc.)

2. Data Processing

Raw patient data is often noisy, incomplete, or inconsistent.

Data Processing involves:

Cleaning the data (handling missing or inconsistent values)

Feature selection/extraction

Normalization or standardization

Splitting the data into training and testing datasets

3. Training Dataset

This is the portion of data used to train the machine learning model.

It is used by the Classification ML Algorithm to learn the patterns or relationships between input features and output labels (e.g., Parkinson's disease present or not).

4. Classification ML Algorithm

This block represents the core machine learning engine.

Various classification algorithms can be used here such as:

Decision Trees

Support Vector Machines (SVM)

Logistic Regression

Neural Networks

The algorithm processes the training data and builds a predictive model by learning from labeled examples.

5. Model

After training, the algorithm generates a trained model.

This model contains the learned parameters that can now predict disease status from new patient data.

6. Test Dataset

This part of the data was held back during training and is used to evaluate the model's performance.

The model is tested on this unseen data to check:

Accuracy

Precision and Recall

F1 Score

ROC-AUC, etc.

Helps determine how well the model generalizes to new data.

Flow Summary:

Patient data is collected.

Data is cleaned and preprocessed.

Data is split into training and test sets.

The training dataset is used to build a classification model.

The model is validated using the test dataset.

Final trained model is used for prediction on new patient data.

Block diagram and its explanation

Key Components of Parkinson's Disease Prediction

1. Definition of Parkinson's Disease

Parkinson's Disease (PD) is a chronic neurodegenerative disorder that primarily affects motor function due to the gradual loss of dopaminergic neurons in the substantia nigra of the brain. It leads to symptoms like tremors, rigidity, bradykinesia (slowness of movement), and postural instability.

2. Symptoms of Parkinson's Disease

a) Motor Symptoms

Tremors (especially at rest)

Bradykinesia (slowed movement)

Muscle rigidity

Impaired balance and coordination

Postural instability

b) Non-Motor Symptoms

Depression and anxiety

Loss of sense of smell (anosmia)

Sleep disturbances

Cognitive impairments

Speech and writing changes

3. Importance of Early Detection

Early diagnosis allows better treatment planning and slows disease progression.

Delayed diagnosis leads to irreversible neuronal damage and poorer outcomes.

Machine Learning can help in identifying subtle early-stage symptoms not detectable through clinical tests alone.

4. Data Used for Detection

Biomedical voice recordings: Frequency, jitter, shimmer, HNR (harmonics-to-noise ratio), NHR (noise-to-harmonics ratio).

Movement data: Gait patterns, tremor intensity.

Handwriting analysis: Changes in stroke size and pressure.

EEG/brainwave signals

Demographic and clinical data (age, sex, UPDRS scores).

5. Dataset Characteristics

Most commonly used datasets:

UCI Parkinson's Dataset (195 voice samples, 31 subjects)

PPMI Dataset (comprehensive clinical, imaging, and biomarker data)

Attributes:

MDVP:Fo(Hz) – Average vocal fundamental frequency

MDVP:Jitter – Variability in frequency

MDVP:Shimmer – Variability in amplitude

Status – 0 (healthy), 1 (Parkinson's patient)

6. Machine Learning Workflow

a) Data Preprocessing

Data cleaning and normalization

Handling missing values and outliers

Feature selection and engineering

Encoding categorical variables

b) Exploratory Data Analysis (EDA)

Descriptive statistics

Distribution of features

Correlation heatmaps

Visualizations: histograms, countplots, boxplots

c) Feature Selection

Important features: Jitter, Shimmer, HNR, NHR, Pitch

Correlation analysis for dimensionality reduction

d) Classification Models Used

Random Forest: Ensemble method using decision trees

XGBoost: Gradient boosting method with superior accuracy

Other models: Logistic Regression, SVM, KNN (explored for comparison)

e) Model Evaluation

Confusion Matrix (TP, TN, FP, FN)

Accuracy, Precision, Recall, F1-score

ROC-AUC curve

7. Model Performance

Random Forest Accuracy: ~92.3%

XGBoost Accuracy: ~94.87%

High precision and recall make these models suitable for medical diagnostics.

8. Challenges and Limitations

Small dataset size can limit generalization

Imbalanced data (fewer PD-positive cases)

Variability in symptom expression

Ethical concerns: privacy, misdiagnosis risks, clinical interpretability

9. Applications and Benefits

Early screening tools in hospitals and clinics

Remote patient monitoring via mobile apps
Support for neurologists in decision-making
Personalized treatment recommendation systems

10. Future Scope

Use of deep learning models (CNNs, LSTMs) for speech and time-series data
Integration with IoT devices for continuous monitoring
Expansion to multimodal datasets (voice, gait, handwriting, EEG)
Development of real-time diagnostic applications

Advantages of the Project

1. Early Detection of Parkinson's Disease

Early diagnosis significantly enhances the effectiveness of treatment. The project enables identifying the disease in its early stages using machine learning (ML) models trained on patient data, such as speech patterns and voice biomarkers.

2. High Accuracy with ML Algorithms

Machine learning algorithms, particularly Random Forest and XGBoost, achieved very high prediction accuracies (up to 94.87%). This demonstrates the reliability and potential of ML for healthcare diagnostics.

3. Data-Driven Diagnosis

The project emphasizes objective, data-driven decision-making as opposed to subjective clinical diagnosis. It utilizes numerical voice features which reduce human bias.

4. Cost-Effective Screening Tool

By automating disease prediction using voice data (a non-invasive and inexpensive input), the system offers a low-cost solution compared to expensive brain scans or genetic testing.

5. Scalability

Once developed, the system can be easily scaled to serve large populations. Cloud-based deployment can make it accessible to hospitals, clinics, and even remote areas with minimal infrastructure.

6. Support for Clinical Decision Making

The model can be used as a decision support system for doctors, providing a second opinion that enhances confidence in the diagnosis and facilitates early treatment planning.

7. Multifeature Learning and Analysis

The use of multiple features like pitch, jitter, shimmer, etc., allows the model to learn complex patterns in data, improving its ability to distinguish between healthy and affected individuals.

8. Automation and Efficiency

Machine learning automates the diagnostic process, reducing the time taken to reach a diagnosis and minimizing dependency on specialist availability.

9. Non-Invasive Nature

The approach relies on voice recordings, which are non-invasive and pose no risk or discomfort to the patient, making it a patient-friendly method.

10. Potential for Integration with Mobile/IoT

The project could be integrated into mobile apps or wearable devices, allowing continuous monitoring and remote diagnosis of Parkinson’s disease symptoms.

11. Improved Patient Outcomes

Timely intervention based on early detection may slow disease progression, resulting in an improved quality of life for patients and lower long-term healthcare costs.

12. Educational Value

The project provides an excellent learning platform for students and researchers interested in the application of artificial intelligence in medicine and biomedical data analysis.

Disadvantages of the Project

1. Limited Dataset Size

The datasets used (e.g., 195 samples, 31 patients, and 23 with Parkinson's) are small, which can limit the generalizability of the trained model. Larger datasets are needed for more robust training.

2. Imbalanced Data

The dataset may be imbalanced, with more samples from non-Parkinson's patients. This can cause the model to be biased toward the majority class and affect prediction accuracy.

3. Dependency on Feature Quality

The success of the model heavily depends on the quality and relevance of extracted features. If key biomarkers are missing or noisy, model performance may degrade.

4. Overfitting Risk

With small or noisy data, machine learning models can overfit, learning patterns that don't generalize well to new, unseen data.

5. Lack of Interpretability

Complex algorithms like XGBoost and Random Forest may act as "black boxes," making it hard for clinicians to interpret why a specific prediction was made.

6. No Real-Time Testing or Deployment

The project appears to be limited to experimental implementation and has not been integrated into a real-time healthcare system for practical testing.

7. Generalization Limitations

Since the data mostly includes voice-based features, the model may not be suitable for patients who have speech impairments unrelated to Parkinson's or other atypical symptoms.

8. No Multimodal Integration

The system does not incorporate other possible data modalities (e.g., gait analysis, MRI, handwriting patterns), which could enhance diagnostic accuracy.

9. Ethical and Privacy Concerns

Using voice data or personal medical records raises ethical issues related to data security, consent, and potential misuse of patient information.

10. Lack of Standardization

There's no universally accepted standard for recording or preprocessing voice features, which may hinder the reproducibility and interoperability of the model in clinical settings.

11. Clinical Acceptance Challenges

Healthcare professionals may be skeptical about replacing or supplementing traditional diagnosis with AI systems due to liability issues, lack of trust, or regulatory constraints.

12. Does Not Address Disease Progression

While the model predicts the presence of the disease, it doesn't provide insights into the stage or progression of Parkinson's, which is vital for treatment planning.

13. Language and Accent Sensitivity

The voice-based system may be influenced by regional accents, speech impairments, or linguistic variations, potentially reducing its accuracy across diverse populations.

14. Training and Maintenance Requirements

To maintain accuracy, models must be retrained with new data, which involves additional costs and technical expertise. Continuous monitoring is needed to ensure consistent performance.

Conclusion

While the project on Parkinson's Disease Prediction using Machine Learning demonstrates powerful advantages such as early diagnosis, high accuracy, and potential clinical utility, it is equally important to consider the technical, clinical, ethical, and practical limitations. Addressing these disadvantages in future iterations by using larger, diverse datasets, incorporating multimodal data, and working closely with healthcare professionals will make the system more robust and acceptable for real-world applications.

Advantages and disadvantages

Applications of Parkinson's Disease Prediction Using Machine Learning

The application of machine learning (ML) in predicting Parkinson's Disease (PD) opens new avenues in medical diagnostics, disease management, healthcare innovation, and patient well-being. The integration of artificial intelligence (AI) into neurological disease detection is not only transforming how medical data is interpreted but also enhancing the ability of clinicians and researchers to make accurate, data-driven decisions. Below are the major applications of this project, described in a detailed and multidisciplinary context.

1. Early Diagnosis and Intervention

One of the most critical applications of this project is the early diagnosis of Parkinson's Disease, often before the symptoms become clinically apparent. Traditional diagnosis methods rely heavily on physical symptoms and clinical evaluations, which might occur only after substantial neurodegeneration. This machine learning-based model can detect subtle patterns in vocal features or other physiological signals, enabling:

Early medical intervention to slow disease progression.

Enhanced patient counseling and planning.

Prevention of misdiagnosis and unnecessary treatments.

Empowering clinicians with supportive diagnostic tools.

2. Remote and Non-Invasive Health Monitoring

By utilizing non-invasive data sources such as voice recordings, gait analysis, or handwriting samples, the system can be deployed in remote and rural settings where access to neurologists and advanced medical infrastructure is limited. This facilitates:

Telemedicine and virtual healthcare.

Continuous patient monitoring from home environments.

Integration with wearable devices and mobile apps.

Health equity by extending services to underserved regions.

3. Decision Support Systems for Clinicians

Machine learning models trained on rich datasets serve as powerful clinical decision support systems (CDSS). These tools can assist neurologists by:

Providing objective and quantitative assessments of motor and non-motor symptoms.

Highlighting correlations not easily visible to human clinicians.

Offering second opinions or risk assessments based on large data repositories.

Reducing diagnostic bias through standardized algorithmic predictions.

4. Personalized Treatment Plans

Parkinson's Disease presents with heterogeneous symptoms, and its progression varies widely among individuals. The predictive model can help in designing personalized treatment plans by:

Stratifying patients based on symptom severity or progression risk.

Recommending tailored therapies, dosages, or physiotherapy regimens.

Monitoring treatment effectiveness using before/after ML analysis.

Adapting medical plans in real-time using live data streams.

5. Parkinson's Disease Progression Modeling

The machine learning system can be extended to track the progression of Parkinson's over time. This has implications for:

Predicting future symptoms or complications.

Adjusting therapeutic strategies dynamically.

Creating longitudinal profiles of patients' health trajectories.

Informing caregivers about expected health changes.

6. Medical Research and Neurological Studies

The data-driven nature of this project contributes significantly to ongoing research in neuroscience and computational biology. Researchers can utilize the findings for:

Identifying biomarkers or indicators of early-stage Parkinson's.

Exploring genetic, demographic, or environmental risk factors.

Designing clinical trials based on patient stratification.

Analyzing cause-effect relationships using advanced analytics.

7. Integration with Smart Health Infrastructure

This predictive system can be integrated into broader smart hospital and e-health frameworks, enabling:

Real-time patient data analysis from EMRs (Electronic Medical Records).

Alerts and notifications for high-risk patients.

Interoperability with hospital databases and monitoring systems.

Seamless communication between healthcare teams via AI dashboards.

8. Educational and Training Tools for Medical Professionals

The system can also be deployed in academic and training settings to teach medical students and junior neurologists about:

Parkinson's disease symptomatology using real-world data.

The role of AI in modern diagnostic tools.

Interpretation of machine learning results and decision boundaries.

Ethical implications of algorithm-assisted diagnosis.

9. Healthcare Cost Reduction

By ensuring accurate and timely diagnosis, this system reduces the economic burden of Parkinson's on healthcare institutions and patients. It supports:

Reducing unnecessary diagnostic imaging or invasive tests.

Lowering hospitalization rates through early management.

Decreasing medication errors with personalized prescriptions.

Optimizing resource allocation in healthcare settings.

10. Empowerment and Engagement of Patients

Through mobile-based interfaces and voice-recording tools, patients can actively engage in their health monitoring, which promotes:

Self-awareness of their health condition.

Regular health tracking without visiting clinics.

Informed decision-making regarding lifestyle and therapy.

Reduced anxiety through data-backed health insights.

11. Public Health Surveillance and Policy Planning

Aggregated and anonymized outputs of such models can support public health agencies by:

Identifying regional patterns in Parkinson's prevalence.

Informing health campaigns and policy interventions.

Allocating funds and infrastructure based on prediction heatmaps.

Planning for future healthcare workforce and geriatric care demands.

12. Cross-Application in Other Neurological Disorders

The methodologies and machine learning frameworks used here can be adapted to study and detect other neurological and neurodegenerative disorders like:

Alzheimer's Disease

Amyotrophic Lateral Sclerosis (ALS)

Multiple Sclerosis (MS)

Huntington's Disease

Essential Tremor Disorders

This opens a broad spectrum of interdisciplinary research and system reuse.

13. Contribution to Artificial Intelligence in Healthcare

Lastly, this project serves as a real-world implementation example for AI in healthcare, contributing to:

Ethical AI development frameworks.

Explainable AI (XAI) studies for clinical interpretability.

Creating open-source tools and reproducible pipelines.

Demonstrating the societal impact of ML for healthcare innovation.

Conclusion

The applications of the Parkinson's Disease Prediction using Machine Learning project are vast and transformative. This system not only offers a significant improvement in the early and accurate diagnosis of PD but also brings disruptive changes to how healthcare

is delivered, managed, and studied. Its impact spans individual patient care, medical research, clinical efficiency, and global health infrastructure. By harnessing the power of data and AI, this project demonstrates the future of predictive, personalized, and precision medicine.

7. Conclusion

In conclusion, the project demonstrates that machine learning algorithms, particularly Random Forest and XGBoost, can effectively predict Parkinson's Disease using voice-based features. By analyzing subtle variations in acoustic parameters that are often undetectable to the human ear, these models offer a powerful tool for early diagnosis. The system achieves impressive accuracy, indicating its potential for integration into clinical practice and health monitoring platforms. This approach not only supports doctors in their diagnostic efforts but also empowers patients to engage in proactive health management. While there are limitations, such as data size and variability, the results validate the feasibility of using AI in neurodegenerative disease detection. Future enhancements including larger datasets, integration of additional biomarkers (like gait and handwriting), and regulatory compliance could make this system a practical reality in the medical field.
